Abstract

Web search indexing is an essential system that powers modern search engines. It automates the process of collection and organization of data from web pages to create an updated index of the web that can be optimally searched. Web search indexing consists of two essential components, a web crawler, in which search engine bots systematically traverse the web to find new or updated content based on rules declared beforehand, followed by the second component which is the indexing of the collected data. The process of web search indexing comes with its own challenges, including performance, managing dynamic content, and answering the question of what is the most relevant content. As the web continues to evolve and grow, the task of web search indexing will remain a key focus of search engine technology and research. The aim of this thesis is to design and implement a generic configurable web search indexing that can be used as a basic tool on different websites and can be further expanded and improved, and scaled. The approach included a simple UI design that allows users to configure and create crawlers and index the generated data.

Acknowledgments

First and foremost, I would like to thank:

- My parents for supporting me during the master's program.
- My wife for her love and support.
- Prof. Dr. Hannah Bast for accepting my topic and for her guidance and supervision.
- M. Sc. Natalie Prange for her thoughtful ideas and suggestions.

1 Introduction

1.1 Motivation

The World Wide Web (WWW) contains an enormous amount of data; this data is increasing each day rapidly. The amount of total data created and replicated is expected to grow to more than 180 zettabytes by 2025 according to Statista. The growth is expected to continue as more smartphones are more and more affordable, and more people can reach the internet. Moreover, due to the COVID-19 pandemic, more companies started offering work remotely, more shops created online stores, and more services switched to cloud-based. This change in society during the last few years has made the internet a vital part of our day-to-day life.

Although the data is available, making a helpful meaning is a challenge. Search engines, for example, try to organize and index that information to make them easily searchable by the end user. Furthermore, collecting data can help spot competitors and have a deeper meaning in the market. Additionally, data scientists are now playing essential roles in most organizations and enterprises to understand consumer needs by collecting and analyzing data from the web.

Although some websites provide APIs to provide organized information about their services, for example, some airline companies provide API that serves information about their flight schedules, other online shops also provide a documented API to get helpful information about their available products. This is not a guaranteed

approach to gathering data, as not all websites offer an excellent documented API. For example, social media websites are reluctant to give information about their users, which is understandable. What if you would like to go through all comments and classify them as spam or not? Depending only on the assumption of having an API for each website is a fragile approach.

Amount of data created, consumed, and stored 2010-2020, with forecasts to 2025

1.2 Contributions

1.3 Chapter Overview

2 Background

Explain the math and notation.

3 Related Work

Give a brief overview of the work relevant for your thesis.

4 Approach

The approach usually starts with the problem definition and continues with what you have done. Try to give an intuition first and describe everything with words and then be more formal like ‘Let g be ...’.

4.1 Problem Definition

Start with a very short motivation why this is important. Then, as stated above, describe the problem with words before getting formal.

4.2 First Part of the Approach

4.3 N-th Part of the Approach

5 Datasets

6 Experimental Evaluation

7 Summary of Results

8 Conclusions and Future Work
